Abstract. Nanostructured NiO particles were prepared by chemical precipitation method. The prepared Nanoparticles were calcined at different temperature and were characterized by X-ray Diffraction (XRD), Fourier Transform Infrared spectroscopy (FTIR), UV-Visible spectroscopy (UV), and Photoluminescence spectroscopy (PL). The XRD result reveals that the crystallite size varies from 12 nm to 45 nm with respect to increase in calcination temperature. FTIR studies shows the presence of NiO group. Optical transmittance and absorption were studied by using UV spectroscopy. Band gap values vareis from 3 to 3.75 eV with calcination. The defect chemistry was analyzed using PL studies. Suitability of synthesis nanoparticles for biomedical application were discused.

Keywords: Metal Oxide Nanoparticles, Nanostructured NiO, Biomedical, Physicochemical

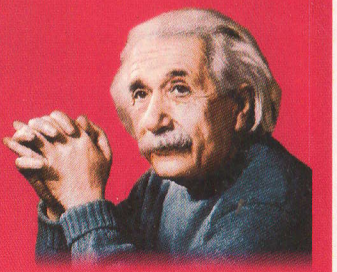

1. Introduction

Metal oxide nanoparticles have interesting strucutural, electrical, magnetic and optical properties. Hence, they are used in various application such as electronics, gas sensor and energy strorage devices[1]. Apart from above said application the metal oxide NPs are used as drug delivery system and Magnetic Resonance Imaging contrasting agent in the biomedical field and as decontaminant in the environment field [2,3]. According to the reports, Various metal oxide nanoparticles have received great interest as antimicrobial agents. Methods of synthesising nanoparticles and their size and morphology are the key factors which influences the effect of antimicrobial agents[4,5].

NiO nanoparticles have drawn lot of interest in recent research, because of high chemical stability, electro catalysis, super conductance characteristics and electron transfer capability. It is an environmentally active material as it finds applications in the adsorption of hazardous dye and inorganic pollutants. Due to their anti- inflammatory properties they are employed in the field of biomedicine. NiO nanoparticle was found to forces poisonous impacts over microscopic organisms and microalgae, because of the capability of prompting oxidative stress and the inclination to discharge nickel particles (Ni^{2+}) inside the cell. NiO have records for their cytotoxic effects, because of their unique properties like surface area, metal ion releasing and adsorbing ability[6].

Iron oxides of nanostructures have promising applications in magnetic recording, magneto-optical, catalysis and biomedical domains. Various polymorphs of iron oxide have widened the possibilities of research based on its structural, magnetic and optical aspects. Fe_3O_4 and α-Fe_2O_3 nanoparticles were synthesized by chemical precipitation method by using the same precursor of $FeSO_4.7H_2O$. Polymorphs of Iron oxide were achieved by varying the complexing agents like NaOH and NH_4OH for Fe_3O_4 and α-Fe_2O_3 synthesis. Structural, vibrational and optical studies of the samples were analyzed using XRD, FTIR and UV-Vis spectroscopy. Structural studies show the cubic and rhombohedra crystal systems of Fe_3O_4 and α-Fe_2O_3. FTIR analysis shows (a) sharp doublet peak in the fingerprint region confirms the presence of α-Fe_2O_3 (b) suppressed single broad peak around the same region explains the formation of Fe_3O_4. A UV-Vis spectrum shows the characteristic absorption maximum of iron oxide with slight variation in energy gap values. Thus the results validates that by varying the complexing agents, phases of Iron oxide can be modified.

High hardness and strength, excellent resistance to heat and corrosion with less weight makes aluminium a suitable material for composities, absorbents, propellants and explosives. The aim of the present work is to study the effect of temperature on the crystallographic modifications on aluminium oxide nanoparticles. Aluminium nitrate non hydrate $Al(NO)_3 .9H_2O$ and Sodium Hydroxide (NaOH) was used to prepare Al_2O_3 nanoparticles by chemical precipitation method. The prepared samples were calcined in air at 200, 400 and 600°C. XRD analysis was carried out to study the crystallinity and the crystallographic parameters such as crystallite size (D), dislocation density (δ), microstrain (ε). The diffraction peaks matches with Al_2O_3 phase of 42-1468 of the JCPDS card. Crystallinity increases with temperature and at 700°C the peaks shows well defined peaks crystallinity. Crystallite size, dislocation density and microstrain increases with temperature. Thus by varying the calcinations temperature crystallographic parameters of aluminium nanoparticles can be tuned.

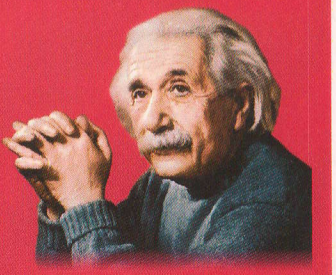

Sample	Crystallite size (D) (nm)	Dislocation density	Microstrain 10^{-3}
Al_2O_3 at 200°C	6.1	6.2510^{14}	0.876
Al_2O_3 at 400°C	9.3	1.2310^{15}	4.893
Al_2O_3 at 600°C	40.2	2.7710^{15}	5.587

Capping agent plays a key role in stabilizing the size and morphology of metal oxides. Poly vinyl alcohol (PVA) acts as a binder with the functional O-H group at the end of the polymer chain. Fe_3O_4 (magnetite) thin films were prepared by simplified SILAR deposition process with PVA as capping agent. The required precursor solution was prepared by adding 0.1 M of Iron (II) Sulfate heptahydrate ($FeSO_4.7H_2O$) and 0.5 M of NH_4OH, 0.001 M of PVA in 100 ml of water with effective stirring. The cleaned glass slides were immersed in precursor solution maintained at 85°C and water for 15 s alternatively for 30 cycles to have well adherent film of thickness around 1.5 µm. The prepared films were annealed at 100 and 300°C. Structural studies show the peak broadening and increase in intensity for PVA capped Fe_3O_4 films annealed at 300°C. The crystallite size decreases with the increase in annealing temperature of PVA capped Fe_3O_4 films. UV-Vis studies reveal that the band gap of the films increases from 2.45 to 2.57 eV with annealing which were calculated from Tauc's plot. The results exhibits that the PVA influences the size and property of Fe_3O_4 thin films.

S.No	Sample	Crystallite size (D) nm	Energy gap (E_g) eV
1.	Undoped	61	2.45
2.	PVA capped Fe_3O_4 films annealed at 100°C	29	2.49
3.	PVA capped Fe_3O_4 films annealed at 300°C	18	2.57

Abstract

Chalcopyrite-based thin film devices (CIGS) contain a so-called buffer layer, made of cadmium sulphide (CdS). Cadmium is highly toxic and therefore, alternative materials are being sought that can replace CdS without losses in its performance. The zinc sulphide (ZnS) is one of the best alternative, to CdS. In the present work, semiconducting ZnS thin films were deposited on glass substrates using successive ionic layer adsorption and reaction (SILAR) technique with different sulfur concentrations (0.2 M to 1 M). The preparative parameters such as concentration, temperature, deposition time, pH of solution have been optimized. The thin films were characterized by using X-ray diffraction (XRD), UV-Vis spectra, photoluminescence (PL) and scanning electron microscope (SEM). The XRD analysis indicates that all the films show an obvious peak corresponding to (111) plane of cubic form ZnS. The average optical transmittance in the visible range is ≥85%. The band gap varies from 3.45 to 4.2 eV. Photoluminescence spectra showed blue emission band (488 nm) and green emission band (521 nm) at an excitation wavelength of 365 nm. The surface morphology of the ZnS thin film is found that the smoothness of the surface varies with the concentration of sulphur. The above discussed results are very much suitable for modern thin film photovoltaic applications.

Synthesis, Spectral Characterization and DNA Cleavage Studies of some Transition Metal (II) Complexes of Schiff base derived from Morpholine

K. Sakthikumar and J. Dhaveethu Raja*
Department of Chemistry, Mohamed Sathak Engineering College, Kilakarai - 623 806, Tamil Nadu, India.

ABSTRACT

Morpholine is a synthetically versatile substrate used for the synthesis of heterocyclic compound and as a raw material for drug synthesis. Morpholine and its derivatives exhibits numerous biological activities such as antibacterial, antiviral, antifungal, anticancer, antitumor, anticonvulsant, antiproliferative, antinflammatory inhibitors, and antidiabetic etc., A series of new mixed ligand Transition metal (II) complexes of Manganese, Cobalt, Nickel, Copper and Zinc have been synthesized from Schiff base (LH) as a primary ligand with interacting diazo ligand phenanthroline as secondary ligand in a 1:1:1 molar ratio. The resulting complexes were characterized by elemental analysis, cyclic voltammetry, Magnetic susceptibility measurements, Molar conductance, Mass, IR, UV-Visible, ^{1}H-NMR, and EPR Spectral techniques. The DNA cleavage activities of all of the complexes were studied by the agarose gel electrophoresis method and the results show that metal complexes can cleave CT-DNA in presence of hydrogen peroxide compared to the ligand. This research may provide valuable insight into the interactions of metal complexes with DNA and cytotoxicity, knowledge that is an excellent back drop for the rational design of promising drugs.
